

What does the `fetch()` method do? How can it be used instead of an AJAX call?

- The `fetch()` method in JavaScript is used to request to the server and load the information on the webpages.
 - Doesn't use XHR so it becomes faster
 - Uses a window method
- Ajax uses XML to request objects
 - Is based on XHR so it is much slower
 - Can report some error codes

In JQuery, what does it mean to "traverse the DOM"?

- Means that once you have a selected element on a webpage, you can move through the page elements relative to your initial selection. Then you can either replace the original selection with a new one or add / subtract elements from it.
